Functions

Function Parts

The two parts of a function are the arguments (formals) and the code (body).

```
gcd = function(long1, lat1, long2, lat2) {
  R = 6371 # Earth mean radius in km
  # distance in km
  acos(sin(lat1)*sin(lat2) + cos(lat1)*cos(lat2) * cos(long2-long1)) * R
}
```

Function Parts

The two parts of a function are the arguments (formals) and the code (body).

```
gcd = function(long1, lat1, long2, lat2) {
   R = 6371 # Earth mean radius in km
   # distance in km
   acos(sin(lat1)*sin(lat2) + cos(lat1)*cos(lat2) * cos(long2-long1)) * R
}
```

```
formals(gcd)
                                                      body(gcd)
                                                     ## {
## $long1
                                                             R = 6371
##
                                                     ##
##
                                                             acos(sin(lat1) * sin(lat2) + cos(lat1) * cos(lat1)
                                                     ##
                                                                 long1)) * R
## $lat1
                                                     ##
##
                                                     ## }
##
## $long2
##
##
## $lat2
```

Return values

There are two ways of returning values in R: explicitly or implicitly.

Explicit - includes one or more return statements

```
f = function(x) {
  return(x*x)
}
```

Implicit - value of the last statement is returned.

```
f = function(x) {
    x*x
}
```

Argument names

When defining a function we are also implicitly defining names for the arguments, when calling the function we can use these names to pass arguments in a different order.

```
f = function(x,y,z) {
    paste0("x=",x," y=",y," z=",z)
}

f(1,2,3)

## [1] "x=1 y=2 z=3"

f(z=1,x=2,y=3)

## [1] "x=2 y=3 z=1"

f(1,2,3,m=1)

## Error in f(1, 2, 3, m = 1): unused argument (m = 1)

f(y=2,1,x=3)

## [1] "x=3 y=2 z=1"

## [1] "x=3 y=2 z=1"
```

Argument defaults

It is also possible to give function arguments default values so that they don't need to be provided every time the function is called.

```
f = function(x,y=1,z=1) {
   paste0("x=",x," y=",y," z=",z)
}

f()

## Error in paste0("x=", x, " y=", y, " z=", z): argument "x" is missing, with no default

f(x=3)

## [1] "x=3 y=1 z=1"

f(y=2,2)

## [1] "x=2 y=2 z=1"
```

Return values

Many of the built in functions in R will return a value, even if you haven't noticed that this is the case. This can be particularly problematic if you are using implicit return values, since you might be returning something you didn't expect.

Some examples,

```
x = y = 5
x
## [1] 5
y
## [1] 5
```

```
z = if (rnorm(1) > 0) {
    "pos"
} else {
    "neg"
}
```

```
## [1] "neg"
```

Return values

Many of the built in functions in R will return a value, even if you haven't noticed that this is the case. This can be particularly problematic if you are using implicit return values, since you might be returning something you didn't expect.

Some examples,

```
x = y = 5

x
## [1] 5

y
## [1] 5
```

```
z = if (rnorm(1) > 0) {
    "pos"
} else {
    "neg"
}
z
```

```
y = 5
```

```
if (rnorm(1) > 0) {
    "pos"
} else {
    "neg"
}
```

```
## [1] "neg"
```

More oddness

```
if (r > 0) {
    print("pos")
} else {
    print("neg")
}

## [1] "pos"

z = if (r > 0) {
    print("pos")
}

print("pos")
}

## [1] "pos"

z

## [1] "pos"
```

More oddness

```
r = rnorm(1)
                                                   z = if (r > 0) {
 if (r > 0) {
   print("pos")
                                                     print("pos")
 } else {
                                                   } else {
   print("neg")
                                                     print("neg")
                                                  ## [1] "pos"
## [1] "pos"
                                                   Z
                                                  ## [1] "pos"
 typeof(print("ABC"))
## [1] "ABC"
## [1] "character"
 z = typeof(print("ABC"))
## [1] "ABC"
Z
## [1] "character"
```

Invisible values

```
f = function(x) {
  invisible(x)
}
```

```
g = function(x) {
    x
}
```

Invisible values

```
f = function(x) {
  invisible(x)
}
g = function(x) {
   x
}
```

```
f(1)
```

[1] 1

Invisible values

```
f = function(x) {
  invisible(x)
}
g = function(x) {
  x
}
```

```
f(1) g(1) ## [1] 1
```

```
  \begin{array}{l}
    x = f(1) \\
    x
  \end{array}
```

[1] 1 ## [1] 1

Even Operators are functions

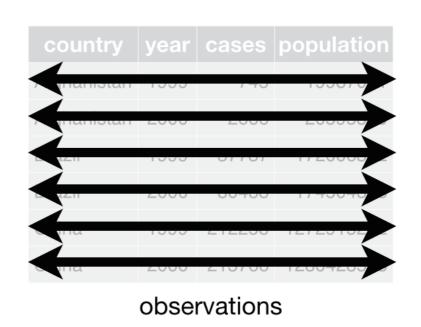

Even Operators are functions

```
`+`
## function (e1, e2) .Primitive("+")
                                                  ## function (e1, e2) .Primitive("|")
typeof(`+`)
                                                   typeof(`|`)
## [1] "builtin"
                                                  ## [1] "builtin"
 `+`(4:1,2)
                                                   `|`(TRUE,FALSE)
## [1] 6 5 4 3
                                                  ## [1] TRUE
4:1 + 2
                                                   TRUE | FALSE
## [1] 6 5 4 3
                                                  ## [1] TRUE
## .Primitive("$")
 , [[,
## .Primitive("[[")
 `names<-`
## function (x, value) .Primitive("names<-")</pre>
```

- Each type of observational unit forms a table

From R4DS - tidy data

Modern data frames

Hadley Wickham / RStudio have a package that modifies data frames to be more modern, or as he calls them surly and lazy.

```
library(tibble)
class(iris)

## [1] "data.frame"

tbl_iris = as_tibble(iris)
class(tbl_iris)

## [1] "tbl_df" "tbl" "data.frame"
```

Fancy Printing

tbl_iris

```
## # A tibble: 150 x 5
      Sepal.Length Sepal.Width Petal.Length Petal.Width Species
##

Pipes in R

You can think about the following sequence of actions - find key, unlock car, start car, drive to school, park.

Expressed as a set of nested functions in R pseudocode this would look like:

```
park(drive(start_car(find("keys")), to="campus"))
```

Writing it out using pipes give it a more natural (and easier to read) structure:

```
find("keys") %>%
    start_car() %>%
    drive(to="campus") %>%
    park()
```

Approaches

All of the following are fine, it comes down to personal preference:

Nested:

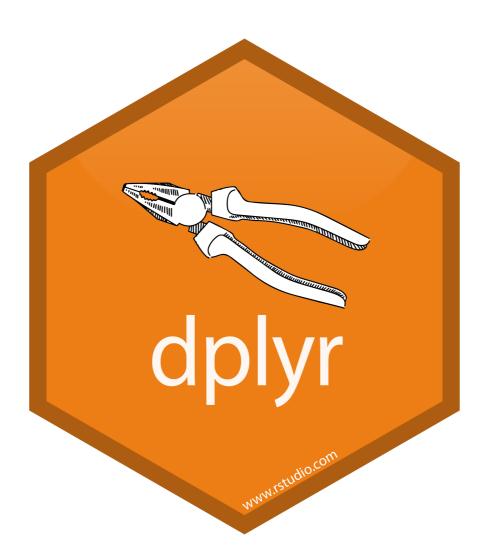

```
h(g(f(x), y=1), z=1)
```

Piped:

```
f(x) %>% g(y=1) %>% h(z=1)
```

Intermediate:

```
res = f(x)
res = g(res, y=1)
res = h(res, z=1)
```

A Grammar of Data Manipulation

dplyr is based on the concepts of functions as verbs that manipulate data frames. Single data frame functions / verbs:

- filter() / slice(): pick rows based on criteria
- select() / rename(): select columns by name
- pull(): grab a column as a vector
- arrange(): reorder rows
- mutate() / transmute(): add new variables
- distinct(): filter for unique rows
- sample_n() / sample_frac(): randomly sample rows
- summarise() / count(): reduce variables to values
- group_by() / ungroup(): modify other verbs to act on subsets
- ... (many more)

dplyr rules

- 1. First argument is *always* a data frame
- 2. Subsequent arguments say what to do with that data frame
- 3. Always return a data frame
- 4. Don't modify in place
- 5. Lazy evaluation magic

Example Data

#

We will demonstrate dplyr's functionality using the nycflights13 data.

```
library(dplyr)
 library(nycflights13)
 flights
## # A tibble: 336,776 x 19
##

Demos

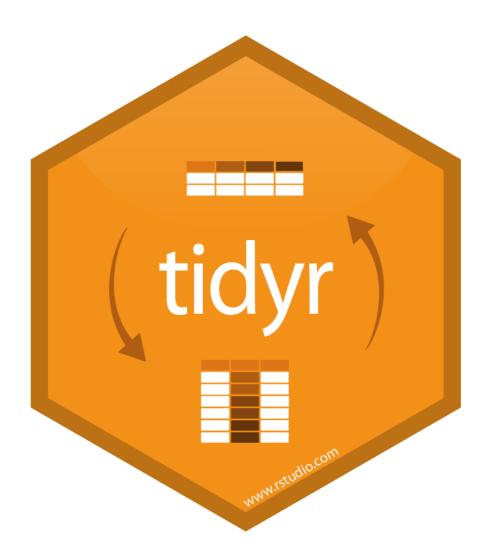

1. How many flights to Los Angeles (LAX) did each of the legacy carriers (AA, UA, DL or US) have in May from JFK, and what was their average duration?

1. What was the shortest flight out of each airport in terms of distance? In terms of duration?

Exercise 1

1. Which plane (check the tail number) flew out of each New York airport the most?

1. Which date should you fly on if you want to have the lowest possible average departure delay? What about arrival delay?

Gather

gather(data, key, value, ..., na.rm = FALSE,
convert = FALSE, factor_key = FALSE)

gather() moves column names into a **key** column, gathering the column values into a single **value** column.

table4a

country	1999	2000		country	year	cases
Α	0.7K	2K	\rightarrow	Α	1999	0.7K
В	37K	80K		В	1999	37K
С	212K	213K		С	1999	212K
				Α	2000	2K
				В	2000	80K
				С	2000	213K
					key	value

Spread

spread(data, key, value, fill = NA, convert = FALSE,
drop = TRUE, sep = NULL)

spread() moves the unique values of a **key** column into the column names, spreading the values of a **value** column across the new columns.

table2

country	year	type	count		country	year	cases	pop
Α	1999	cases	0.7K	_	Α	1999	0.7K	19M
Α	1999	рор	19M	-	Α	2000	2K	20M
Α	2000	cases	2K		В	1999	37K	172M
Α	2000	рор	20M		В	2000	80K	174M
В	1999	cases	37K		С	1999	212K	1T
В	1999	рор	172M		С	2000	213K	1T
В	2000	cases	80K					
В	2000	рор	174M					
С	1999	cases	212K					
С	1999	рор	1T					
С	2000	cases	213K					
С	2000	рор	1T					

key value

Separate

```
separate(data, col, into, sep = "[^[:alnum:]]
+", remove = TRUE, convert = FALSE,
extra = "warn", fill = "warn", ...)
```

Separate each cell in a column to make several columns.

table3

country	year	rate		country	year	cases	рор
Α	1999	0.7K / 19M		Α	1999	0.7K	19M
Α	2000	2K/20M	—	Α	2000	2K	20M
В	1999	37K / 172M		В	1999	37K	172
В	2000	80K / 174M		В	2000	80K	174
С	1999	212K/1T		С	1999	212K	1T
С	2000	213K / 1T		С	2000	213K	1T

Unite

unite(data, col, ..., sep = "_", remove = TRUE)

Collapse cells across several columns to make a single column.

table5

country	century	year		country	year
Afghan	19	99		Afghan	1999
Afghan	20	0	—	Afghan	2000
Brazil	19	99		Brazil	1999
Brazil	20	0		Brazil	2000
China	19	99		China	1999
China	20	0		China	2000

unite(table5, century, year, col = "year", sep = "")

Example 1 - Grades

Is the following data tidy?

```
(grades = tibble(
