# **Functions**

### **Function Parts**

The two parts of a function are the arguments (formals) and the code (body).

```
gcd = function(long1, lat1, long2, lat2) {
   R = 6371 # Earth mean radius in km
   # distance in km
   acos(sin(lat1)*sin(lat2) + cos(lat1)*cos(lat2) * cos(long2-long1)) * R
}
```

```
formals(gcd)
                                                      body(gcd)
                                                     ## {
## $long1
##
                                                     ##
                                                             R = 6371
##
                                                             acos(sin(lat1) * sin(lat2) + cos(lat1) * cos(lat1)
                                                     ##
## $lat1
                                                     ##
                                                                 long1)) * R
##
                                                     ## }
##
## $long2
##
##
## $lat2
```

### **Return values**

There are two ways of returning values in R: explicitly or implicitly.

Explicit - includes one or more return statements

```
f = function(x) {
  return(x*x)
}
```

*Implicit* - value of the last statement is returned.

```
f = function(x) {
    x*x
}
```

### **Argument names**

When defining a function we are also implicitly defining names for the arguments, when calling the function we can use these names to pass arguments in a different order.

```
f = function(x,y,z) {
  paste0("x=",x," y=",y," z=",z)
}

f(1,2,3)

## [1] "x=1 y=2 z=3"

f(z=1,x=2,y=3)

## [1] "x=2 y=3 z=1"

f(1,2,3,m=1)

## Error in f(1, 2, 3, m = 1): unused argument (m = 1)
```

# **Argument defaults**

It is also possible to give function arguments default values so that they don't need to be provided every time the function is called.

```
f = function(x,y=1,z=1) {
   paste0("x=",x," y=",y," z=",z)
}

f()

## Error in paste0("x=", x, " y=", y, " z=", z): argument "x" is missing, with no default

f(x=3)

## [1] "x=3 y=1 z=1"

f(y=2,2)

## [1] "x=2 y=2 z=1"
```

### **Return values**

Many of the built in functions in R will return a value, even if you haven't noticed that this is the case. This can be particularly problematic if you are using implicit return values, since you might be returning something you didn't expect.

Some examples,

```
x = y = 5

x
## [1] 5

y
## [1] 5
```

```
z = if (rnorm(1) > 0) {
   "pos"
} else {
   "neg"
}
```

```
## [1] "neg"
```

```
y = 5
```

```
if (rnorm(1) > 0) {
    "pos"
} else {
    "neg"
}
```

```
## [1] "pos"
```

### More oddness

```
r = rnorm(1)
 if (r > 0) {
                                                   z = if (r > 0) {
   print("pos")
                                                     print("pos")
 } else {
                                                   } else {
   print("neg")
                                                     print("neg")
## [1] "neg"
                                                  ## [1] "neg"
                                                   Ζ
                                                  ## [1] "neg"
 typeof(print("ABC"))
## [1] "ABC"
## [1] "character"
 z = typeof(print("ABC"))
## [1] "ABC"
Ζ
## [1] "character"
```

## **Invisible values**

```
f = function(x) {
  invisible(x)
}
g = function(x) {
  x
}
```

```
f(1) g(1) ## [1] 1
```

```
  \begin{array}{l}
    x = f(1) \\
    x
  \end{array}
```

```
## [1] 1 ## [1] 1
```

### Modern data frames

Hadley Wickham / RStudio have a package that modifies data frames to be more modern, or as he calls them surly and lazy.

```
library(tibble)
class(iris)

## [1] "data.frame"

tbl_iris = as_tibble(iris)
class(tbl_iris)

## [1] "tbl_df" "tbl" "data.frame"
```

# **Fancy Printing**

#### tbl\_iris

```
## # A tibble: 150 x 5
      Sepal.Length Sepal.Width Petal.Length Petal.Width Species
##

# Pipes in R

You can think about the following sequence of actions - find key, unlock car, start car, drive to school, park.

Expressed as a set of nested functions in R pseudocode this would look like:

```
park(drive(start_car(find("keys")), to="campus"))
```

Writing it out using pipes give it a more natural (and easier to read) structure:

```
find("keys") %>%
    start_car() %>%
    drive(to="campus") %>%
    park()
```

## **Approaches**

All of the following are fine, it comes down to personal preference:

#### Nested:

```
h(g(f(x), y=1), z=1)
```

#### Piped:

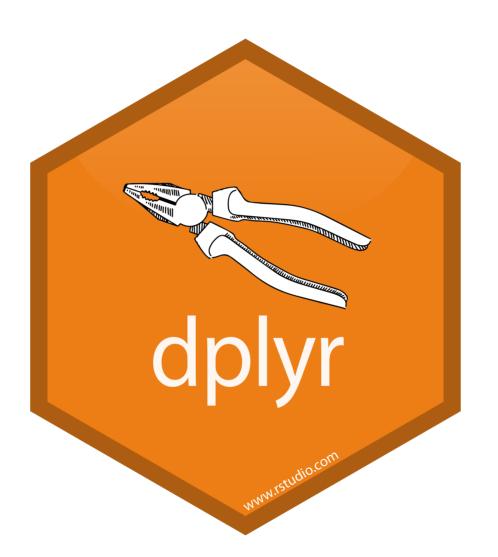

```
f(x) %>% g(y=1) %>% h(z=1)
```

#### Intermediate:

```
res = f(x)
res = g(res, y=1)
res = h(res, z=1)
```

## What about other arguments?

Sometimes we want to send our results to an function argument other than first one or we want to use the previous result for multiple arguments. In these cases we can refer to the previous result using ..

### A Grammar of Data Manipulation

dplyr is based on the concepts of functions as verbs that manipulate data frames. Single data frame functions / verbs:

- filter()/slice(): pick rows based on criteria
- select() / rename(): select columns by name
- pull(): grab a column as a vector
- arrange(): reorder rows
- mutate() / transmute(): add new variables
- distinct(): filter for unique rows
- sample\_n() / sample\_frac(): randomly sample rows
- summarise() / count(): reduce variables to values
- group\_by() / ungroup(): modify other verbs to act on subsets
- ... (many more)

# dplyr rules

- 1. First argument is always a data frame
- 2. Subsequent arguments say what to do with that data frame
- 3. Always return a data frame
- 4. Don't modify in place
- 5. Lazy evaluation magic

### **Example Data**

## #

We will demonstrate dplyr's functionality using the nycflights 13 data.

```
librarv(dplvr)
 librarv(nvcflights13)
 flights

### **Demos**

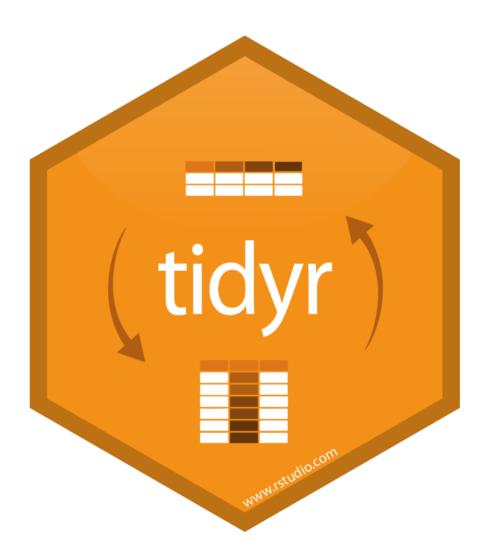

1. How many flights to Los Angeles (LAX) did each of the legacy carriers (AA, UA, DL or US) have in May from JFK, and what was their average duration?

1. What was the shortest flight out of each airport in terms of distance? In terms of duration?

### **Exercise 1**

1. Which plane (check the tail number) flew out of each New York airport the most?

1. Which date should you fly on if you want to have the lowest possible average departure delay? What about arrival delay?

### **Gather**

country	1999	2000		country	year	cases
Α	0.7K	2K	$\rightarrow$	Α	1999	0.7K

### **Example 1 - Grades**

Is the following data tidy?

```
(grades = tibble(
  name = c("Alice", "Bob", "Carol", "Dave"),
  hw_1 = c(19, 18, 18, 19),
  hw_2 = c(19, 20, 20, 19),
  hw_3 = c(18, 18, 18, 18),
  hw_4 = c(20, 16, 17, 19),
  exam_1 = c(89, 77, 96, 86),
  exam_2 = c(95, 88, 99, 82)
))
```

```
## # A tibble: 4 x 7
          hw_1 hw_2 hw_3 hw_4 exam_1 exam_2
##
    name
  <chr> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
##
## 1 Alice
          19 19 18
                            20
                                        95
          18 20 18 16 77 88
18 20 18 17 96 99
## 2 Bob
## 3 Carol
        19 19 18 19
## 4 Dave
                                 86
                                      82
```

How would we calculate a final score based on the following formula,

$$score = 0.6 \frac{\sum hw_i}{80} + 0.4 \frac{\sum exam_j}{200}$$

### Semi-tidy approach
